58 1 Introduction

59 The OASIS Digital Signature Services (DSS) TC has produced a number of specification
60 documents. This document attempts to provide an overview of DSS and the roles played by the
61 various specifications.

62 1.1 Overview of DSS

63 The DSS specifications describe two XML-based request/response protocols – a signing protocol
64 and a verifying protocol. Through these protocols a client can send documents to a server and
65 receive back a signature on the documents; or send documents and a signature to a server, and
66 receive back an answer on whether the signature verifies the documents.

67 These operations could be useful in a variety of contexts – for example, they could allow clients to
68 access a single corporate key for signing press releases, with centralized access control,
69 auditing, and archiving of signature requests. They could also allow clients to create and verify
70 signatures without needing complex client software and configuration.

71 The signing and verifying protocols are chiefly designed to support the creation and verification of
72 XML signatures [XMLSig], , and CMS signatures [RFC3369]. These protocols can also be used
73 to create and verify time-stamps, either in binary format as defined in [RFC3161] or to an XML
74 time-stamp structure as defined in DSS. These protocols may also be extensible to other types of
75 signatures and timestamps, such as PGP signatures.

76 It is expected that the signing and verifying protocols will be *profiled* to meet many different
77 application scenarios. In anticipation of this, these protocols have only a minimal set of required
78 elements, which deal with transferring “input documents” and signatures back and forth between
79 client and server.

80 The current DSS specifications and published papers about DSS are available via the DSS
81 Technical Committee web site at:

82 <http://www.oasis-open.org/committees/dss>

83 1.2 DSS Specifications

84 The DSS specification consist of a “Core Protocols, Elements, and Bindings” specification (the
85 Core) and a number of profiles.

86 The Core specification provide the basic protocols and elements which are adapted to support
87 specific use cases in the DSS profiles. The Core consists of:

- 88 - Skeleton protocols for signing and verifying
- 89 - Optional elements that can be “mixed in” to the skeleton protocols to support the
90 requirements of the different profiles. This includes an XML timestamp and elements to
91 control a range of approaches to creation and verification of signatures,
- 92 - A range of transport and security bindings that selected as required by profiles.

93 The DSS profiles specify the options and bindings to be used with the skeleton protocols to meet
94 the requirements of a particular application or use case. A profile may also specify additional
95 elements and / or bindings where necessary to meet its own particular needs.

96 Profiles are either abstract or concrete. Concrete profiles provide a complete selection of the
97 options giving the basis for interoperability: products implementing concrete profiles should be
98 compatible at the level of protocol defined by DSS. Abstract profiles add some functionality or
99 options to the core that can be inherited by concrete profiles, or by other abstract profiles (and in
100 some cases, concrete profiles can be made more concrete through inheritance as well).

101 These relationships can be visualized as an inheritance graph, with the core as the root node,
102 and a directed acyclic graph of profiles and sub-profiles extending below it.
103 The DSS TC has produced several profiles so far, and is likely to produce further profiles in the
104 future. Below is a summary of the existing DSS profiles.
105

106 2 Current DSS Profiles

107 2.1 Time-stamp Profile

108 2.1.1 Overview

109 The Time-stamp profile define the use of the DSS Core protocols to support creation and
110 verification of time-stamps. The profile includes support for the creation of XML Time-stamps as
111 defined in the Core and binary time-stamps as defined in [RFC 3161].

112 2.1.2 Relationship to other Profiles

113 None.

114 2.2 Asynchronous Profile

115 2.2.1 Overview

116 Although most applications of the OASIS Digital Signature Service supply the results
117 immediately, there is a demand for deferred delivery of results. For example, the German
118 Signature Law explicitly requires the commitment of the certificate holder or at least a time slot for
119 the certificate holder to deny the signing request.

120 This abstract profile defines a simple mechanism for asynchronous signing and verification
121 requests. Concrete profiles that use this abstract profile allow the client to submit a request which
122 the server doesn't respond to right away. Instead, the client can poll the server until the response
123 is ready.

124 2.2.2 Relationship to other Profiles

125 This profile is a parent of the code-signing profile.

126 2.3 Code-Signing Profile

127 2.3.1 Overview

128 Code-signing allows the recipient of a software program to receive assurances regarding the
129 origin and integrity of a program. The recipient may use this information to make a trust decision
130 on whether to install or execute the program.

131 Centralizing the generation of signatures in the code-signing process allows for the roles of the
132 software developer and the code signer to be separated. This has the advantage that keys used
133 for signing software programs can be better managed, access to the keys can be better
134 controlled, audit trails can be centrally kept, event records can be reliably archived, and signing
135 policies can be rigorously enforced.

136 This abstract profile provides a basic framework for code-signing independent of any specific
137 signature schemes or formats. Specifying the use of specific signature schemes and formats is
138 left to concrete sub-profiles. For instance, a code-signing profile should be defined for Java 2
139 Micro Edition code-signing and Authenticode code-signing.

140 2.3.2 Relationship to other Profiles

141 This profile is a child of the asynchronous profile, and a parent of the J2ME code-signing profile.

142 **2.4 J2ME code-signing profile**

143 **2.4.1 Overview**

144 This specification provides a concrete profile based on the Code-Signing Profile for requesting
145 the generation of signatures as specified in the Java 2 Micro Edition (J2ME), Mobile Information
146 Device Profile 2.0 [MIDP 2.0].

147 **2.4.2 Relationship to other Profiles**

148 This profile is a child of the asynchronous profile, and the code-signing profile.
149

150 **2.5 Entity Seal Profile**

151 **2.5.1 Overview**

152 This profile supports creation and validation of a “seal” created by a given Entity or Organization
153 on electronic data.

154 The seal is a form of electronic signature which:

- 155 a) protects the integrity of the document,
- 156 b) includes the time at which the seal was applied proving that the data existed at the given
157 time,
- 158 c) includes the identity of the entity requesting the seal,

159 may include a statement of intent for applying the seal.

160 This profile is concrete except for the security binding, which must be specified before using this
161 in a particular environment.

162 **2.5.2 Relationship to other Profiles**

163 None.
164

165 **2.6 Electronic Postmark (EPM) Profile**

166 **2.6.1 Overview**

167 The Electronic PostMarking service [EPM] is a Universal Postal Union (UPU) endorsed standard
168 aimed at providing generalized signature creation, signature verification, timestamping, and
169 receipting services for use by and across Postal Administrations and their target customers.

170 Although the total scope and functional coverage of the EPM's service offering are outside the
171 immediate scope of the DSS initiative, the UPU wishes to offer its client base a DSS-compliant
172 subset of the EPM for clients who wish to maintain OASIS compliance in the core areas of
173 signature and timestamp creation and verification.

174 **2.6.2 Relationship to other Profiles**

175 None.
176

177 **2.7 German Signature Law Profile**

178 **2.7.1 Overview**

179 This abstract profile supports creation and validation of qualified signatures according to the
180 guidelines given by the German signature law [**SigG**] and its associated regulations. The EU has
181 certified that the German signature law complies with the European legal framework, so this
182 profile may be used as a template for national profiles all over Europe.

183 **2.7.2 Relationship to other Profiles**

184 None.

185 **2.8 AdES Profile**

186 **2.8.1 Overview**

187 This set of profiles supports the creation and verification of XML and binary Advanced Electronic
188 Signatures as defined in [**XAdES**] and [**TS 101 733**].

189 **2.8.2 Relationship to other Profiles**

190 None.

191

192 **2.9 Signature Gateway Profile**

193 **2.9.1 Overview**

194 The Signature Gateway profile specifies the use of DSS to support the transform of a signature.
195 This Signature Gateway transforms both *signing technology* and *credential logistics*. The signing
196 technology specifies the mechanisms through which one creates and verifies a signature.
197 Example technologies include, but are not limited to photocopied signatures, signatures using
198 public key infrastructures, and signatures defined using symmetric keying material. Credential
199 logistics, describes the means to distribute credentials to remote parties; and the associated
200 vehicle for distributing trust. Although electronic means allows communication at a distance,
201 geographic separation increases the difficulty of trusting one's peers. Credentials overcome
202 many of the geographic impediments to trust; and the associated logistics securely define the
203 means of managing the credential lifecycle, e.g., distribution, revocation, renewal, and retirement.

204 **2.9.2 Relationship to other Profiles**

205 None.
